Molenplaat

HyMap sensor

- Geometrically, radiometrically and atmospherically corrected
- Characteristics

Date	06-08-2004
Moment of overflight	Between 11.40 and 12.00
Spatial resolution	4x4 m pixel size

Spectral Configuration of HyMap™			
Module	Spectral range	Bandwidth across module	Average spectral sampling interval
VIS	0.45 – 0.89 μm	15 – 16 nm	15 nm
NIR	0.89 – 1.35 μm	15 – 16 nm	15 nm
SWIR1	1.40 – 1.80 μm	15 – 16 nm	13 nm
SWIR2	1.95 – 2.48 μm	18 – 20 nm	17 nm

 - erodibility

5. Conclusions

Molenplaat

- Intertidal mudflat in the Westerschelde estuary
- Located between ± 1 meter relative to the mean tidal level. The mean tidal range is approximately 5 meters. The average period of emersion varies between 2 – 4 hours and 8 hours, for the highest location, per tidal cycle
- One of the largest wading bird populations in western Europe
- The estuary is a site of heavy industry, and is an important commercial shipping route

 - chlorophyll a
and primary
productivity
 - erodibility

5. Conclusions

Objectives

- Investigation of the most important biological and physical parameters on the Molenplaat using HyMap imagery and field data
 - ❖ Pigment (chlorophyll a) content
 - ❖ Sediment grain size distribution
 - ❖ Water content
 - ❖ Organic matter content
- In addition, value-added products with relevance for coastal zone management will be produced
 - ❖ High-resolution map of primary production
 - ❖ Ecotope classification
 - ❖ Map of sediment stability
- Quantification of time-dependent changes during a tidal cycle in the reflectance of the sediment
- Consortium of five partners

5. Conclusions

Methods

1. classification of ground truth

Grain size: mud (clay&silt>30%), muddy sand (clay&silt<30% and >15%), fine sand (clay&silt<15%)

Chlorophyll a: low (0-20mg/m²), intermediate (20-40mg/m²), high (>40mg/m²)

Organic matter: low (0-2%), intermediate (2-4%), high (>4%)

Moisture content: dry (0-20%), semi-dry (20-30%), wet (30-40%), saturated (>40%)

2. supervised > VITO

Feature selection procedure

Multiple binary classification based on linear discriminant Analysis for each parameter

Integration of individual classifications into on ecotope map

3. unsupervised > KUL

Clustering of pixels using hierarchical PCT and two PC

Merging of classes based on separability measure

Labelling of classes using field data

1. Study area

2. Objectives

3. Field Work

4. Methods

- Approach 1:
Supervised
classification
- Approach 2:
Unsupervised
classification
- End-user
products
 - ecotope
 - chlorophyll a
and primary
productivity
 - erodibility

5. Conclusions

Approach 1: Supervised classification

A. Feature selection procedure

- SFFS: sequential floating forward selection (Pudil, 1994)
- Principle: search for the best subset of features to obtain the highest classification acc's
 - > Ideally: considering all possible combinations of features, but too labour intensive
 - > hence, sub-optimal search algorithm: SFFS

First step: search for the one, best feature

Second step: add a second feature to obtain highest acc. with this subset

Third step: adding third feature but also removing least significant feature as long as cost function increases (= floating aspect)

X'th step: search stops if acc. decreases when adding new features

SFFS is run for each of the 4 parameters to be classified: median grain size, water content, chl a concentration, organic matter content

▪ [Approach 1: Supervised classification](#)

▪ Approach 2: Unsupervised classification

▪ End-user products
- ecotope
- chlorophyll a and primary productivity
- erodibility

5. Conclusions

B. Supervised classification

>> Fisher's Linear Discriminant analysis

Principle

- Make a new linear function $y=w^t x$ for which ratio “between class scatter” to “within class scatter” is maximized > max class separability!
- 2-class problem: projection to 1-dimension (y)
- 3-class problem: projection to 2-dimensions
 - Threshold y_{thresh} discriminates two classes

1. Study area

2. Objectives

3. Field Work

4. Methods

- Approach 1:
Supervised classification
- Approach 2:
Unsupervised classification
- End-user products
 - ecotope
 - chlorophyll a and primary productivity
 - erodibility

5. Conclusions

B. Supervised classification

>> Fisher's Linear Discriminant analysis

Maximum Voting: 4 class example

Bin Classifier	Result
1-2	2
1-3	3
1-4	4
2-3	2
2-4	4
3-4	4

2. Objectives

3. Field Work

4. Methods

- Approach 1:
Supervised
classification
- Approach 2:
Unsupervised
classification
- End-user
products
 - ecotope
 - chlorophyll a
and primary
productivity
 - erodibility

5. Conclusions

Sediment stability map

1. Study area

2. Objectives

3. Field Work

4. Methods

- Approach 1:
Supervised
classification
- Approach 2:
Unsupervised
classification
- End-user
products
 - ecotope
 - chlorophyll a
and primary
productivity
 - erodibility

5. Conclusions

Conclusions

The four parameters under investigation are highly correlated.

High accuracies were obtained in the supervised classifications of individual parameters (o.m.: 87%, grain size: 86%, chl a: 80%, water content: 81%).

In the feature selection procedure, bands in the VIS and NIR were chosen for each parameter, indicating that a common VNIR sensor is suitable for this application.

Unsupervised classification is useful in less accessible and remote intertidal areas.

Chlorophyll, primary production and sediment stability maps can be used for qualitative analysis.

Further work

- quantification of the influence of different environmental variables on a reflectance signal
- time-dependent changes of properties of intertidal mudflats during a tidal cycle
- comparison of supervised and unsupervised classification results
